一、实验目的

- 1. 熟悉 pluto 的使用方法。在发送端产生信号,并采用多种调制方法对发送信号进行调制处理。
 - 2. 接收机进行信号的接收,并对所获信号进行调制方式的自动识别。

二、实验原理

本实验实现的调制方式识别有单音信号、FM 调制、BPSK 调制、QPSK 调制、2FSK 调制、4FSK 调制,通过信号调制后频谱的变化来判断调制方式。单音信号只有一个频率即频谱只有一个尖峰;由 2FSK 调制和 4FSK 调制原理可知,2FSK 调制信号对应 01 序列有两个不同的频率,调制后有频谱会出现两个尖峰,而 4FSK 信号调制后出现 4 个尖峰。FM 调制、BPSK 调制、QPSK 信号调制后信号频谱均会有一定带宽,因此判断 FM、BPSK、QPSK 调制方式需要有进一步的处理如下。

1. FM 调制方式识别方法

FM 线性调频后信号可以表示为

$$x_1(t) = A \cdot e^{j\pi kt^2 + 2j\pi f_c t + \varphi_0}$$
(2.1)

其中k为调频率,k = B/T,(B为带宽,T为时宽),将x(t)平方后可以得到新的信号

$$x_2(t) = A^2 \cdot e^{2j\pi kt^2 + 4j\pi f_c t + 2\phi_0}$$
 (2.2)

可以看到,经过平方后信号由原信号 $x_1(t)$ 调频率k、中心频率 f_c 变化为 $x_2(t)$ 的2k调频率、 $2f_c$ 中心频率,所以信号频谱会发生搬移并且带宽变大。

2. BPSQ 调制方式识别

BPSQ 调制原理为,对于一段 01 序列,信号遇到 1 时会产生大小为 pi 的相位变化。原信号为

$$x_1(t) = A \cdot e^{2j\pi f_c t + \varphi_0} \tag{2.3}$$

若接收到的码元为 0 信号不发生变化,若码元为 1,则原信号相位加π变成

$$x_2(t) = A \cdot e^{2j\pi f_c t + \pi + \varphi_0}$$
 (2.4)

此时产生的信号频谱有一定带宽 f_w ,旁瓣带宽较大。若将 BPSK 调制后的信号平方,码元为 0 所对应的信号:

$$y_1(t) = A^2 \cdot e^{4j\pi f_c t + 2\varphi_0} \tag{2.5}$$

码元为1对应的信号为:

$$y_2(t) = A^2 \cdot e^{4j\pi f_c t + 2\pi + 2\varphi_0} \tag{2.6}$$

将该信号欧拉变换后可以得到,信号 $y_1(t)$ 与 $y_2(t)$ 相位相差 2π ,所对应的值不变,即 $y_2(t)$ 与 $y_1(t)$ 可认为是相同信号,因此,BPSK 调制后的信号平方,信号由原来两个信号 $y_1(t)$, $y_2(t)$ 的叠加,变成可视为同一信号的 $y_1(t)$ 或者 $y_2(t)$ 。带宽由平方前的信号 f_w 转为一个尖峰,带宽变小。

3. QPSK 调制方式识别:

根据 QPSK 调制原理,两列 01 码元序列分两路输入,每一路一个码元相加后形成 2bit 的码元组,对于接收到的码元组 00,01,10,11 分别对应相位为 $0,\frac{\pi}{2},\pi,\frac{3\pi}{2}$,中心频率为 f_c 的 信号 $y_1(t)$,此时带宽为 f_w 。将 QPSK 调制后的信号平方之后可以得到中心频率为 $2f_c$,相位为 $0,\pi,2\pi,3\pi$ 的信号 $y_2(t)$,此时的信号运用欧拉公式展开,可以认为是相位相差 π 的两个信号结合,即 BPSK 调制后的信号,旁瓣带宽较大。再将 $y_2(t)$ 平方即 BPSK 信号平方,原理同上述 BPSK 信号调制识别,最终信号 QPSK 调制后的信号 $y_1(t)$ 经过四次方后信号频谱变为一个

尖峰,中心频率变成4倍。

综上所述,区别 FM、BPSK、QPSK 信号调制方式, FM 调制后的信号平方后带宽变宽, BPSQ 调制后信号的频谱有一定带宽, 旁瓣带宽较大, 信号平方后频谱的带宽变窄只有一个尖峰; QPSK 调制的信号平方后有一定带宽, 旁瓣较大, 四次方后变成一个尖峰。

三、实现过程

本项目通过平方等一系列操作观察信号频谱来识别信号,目前可实现单音、线性调频、2FSK、4FSK、BPSK、QPSK等六种信号。并通过 ADALM-PLUTO 作为发射机和接收机实现信号的收发。

本项目的架构分为用于收发的主函数 main.m,集成信号生成器函数 Signal_generation.m,其中引用了生成单音信号的函数 Single_Signal.m、生成单音信号的函数 Single_Signal.m、生成单音信号的函数 Single_Signal.m、生成线性调频信号的函数 LFM_Signal.m、生成 2FSK 信号的函数 FSK2_Signal.m、生成 4FSK 信号的函数 FSK4_Signal.m、生成 BPSK 信号的函数 BPSK_Signal.m、生成 QPSK 信号的函数 Single_Signal.m,以及信号识别函数 SignalRecognition.m,其中引用了计算带宽的函数 calc_B.m 和峰值检测函数 FindPeakNum.m。

单音信号我们通过将信号进行平方后,对平方前后信号的带宽进行比较,若带宽的变化不大,即在我们设置的动态范围之内,可以认为该信号为单音信号。

LFM 信号我们通过将信号进行平方后,对平方前后信号的带宽进行比较,若带宽的变宽,即大于我们设置的动态范围,可以认为该信号为 LFM 信号。但是此方法误差较大,容易与其他信号混淆,因此本项目还结合了频谱的阈值,即在 LFM 信号带宽范围内所有频率的峰值都大于阈值,以及 DFT 算法,即将原信号与延时信号共轭卷积后只剩下一个单音信号,即可认为该信号为 LFM 信号。

2FSK 信号与 4FSK 信号我们都是通过检测信号发峰值来进行检测的,当检测出来有两个峰值时,我们认为该信号为 2FSK 信号,当检测出来有四个峰值时,我们认为该信号为 4FSK 信号。

BPSK 信号和 QPSK 信号我们通过将信号进行平方后,对平方前后信号的带宽进行比较,若带宽的变窄,即大于我们设置的动态范围,可以认为该信号为 BPSK 信号。但是该检测方法易与 QPSK 信号混淆,因此我们还对信号进行四次方处理,QPSK 信号在平方后变为一个单音信号,再次平方后信号频谱带宽几乎没什么变化,而 QPSK 信号平方后变为 BPSK 信号,再次平方后变为单音信号,四次方后信号频率带宽还是会变窄。通过比较原信号、平方后信号,四次方后信号的频谱带宽的变化来识别,若平方后带宽变窄,但是四次方后与平方后带宽变化不大,则该信号为 BPSK 信号,若平方后带宽变窄,且四次方后与平方后带宽依旧变窄,则该信号为 BPSK 信号。

四、结论成果

我们生成了上述的六种信号了,通过 ADALM-PLUTO 进行数据传输和接受,并将接收到的数据进行了识别,最终得到的六种信号的结果如下图所示:
